(54) Speed change controller for automatic transmission

(57) In a vehicle transmission wherein plural speed change ratios from a highest speed change ratio to a lowest speed change ratio are selectively applied according to a command input by a driver, a real speed change ratio of the transmission is detected. It is determined whether or not the transmission is performing a shift-down based on the input command and the real speed change ratio. A shift-down limit speed change ratio is determined based on the speed change ratio

before the shift-down operation is performed, and when the engine brake of the vehicle is operating, the transmission is controlled so as not to apply a speed change ratio larger than this shift-down limit speed change ratio. Due to this, the driver does not experience an excessive engine braking sensation even when an extreme speed change command is issued.

Description

FIELD OF THE INVENTION

This invention relates to a speed change controller for use with an automatic transmission of a vehicle in which a manual operation mode is provided.

BACKGROUND OF THE INVENTION

In an automatic transmission for a vehicle, the speed change ratio is varied automatically according to vehicle speed or throttle opening, etc. Apart from the automatic operation mode, a speed change control device which permits manual operation by a driver is disclosed in Tokkai Hei 5-322022 published by the Japanese Patent Office in 1993.

This device comprises an operating lever for the driver to input a shift-up command or shift-down command into the speed change control device. In manual mode speed change, the automatic transmission performs shift-up or shift-down operations according to the operating direction and operating frequency of the operating lever. That is to say when, for example, the operating lever is moved twice in the shift-down direction from fourth speed, a shift-down to second speed from fourth speed is performed.

However, when operations of the operating lever are successively performed in the same direction, the speed changes abruptly from fourth speed to first speed in a short time, and as a result the driver experiences an excessive engine braking sensation.

SUMMARY OF THE INVENTION

It is therefore an object of this invention to limit manual speed change operations in an automatic transmission comprising a manual mode speed change, such that a driver would not experience an excessive engine braking sensation.

In order to achieve the above object, this invention provides a speed change controller for outputting a speed change ratio command signal to a transmission of a vehicle for selectively applying plural speed change ratios from a largest speed change ratio to a smallest speed change ratio according to a command input by a driver. The vehicle comprises an engine being capable of exerting an engine brake on the vehicle according to a reduction operation input by the driver.

The controller comprises an engine brake sensor for detecting whether or not the vehicle is under the action of the engine brake, a real speed change ratio detection sensor for detecting a real speed change ratio of the transmission, and a microprocessor programmed to determine whether or not the transmission is performing a shift-down operation based on the real speed change ratio and the speed change ratio command signal, determine a shift-down limit speed change ratio

based on the speed change ratio before the shift-down operation is performed, and refrain from outputting a speed change ratio command signal corresponding to a speed change ratio larger than the shift-down limit speed change ratio when the vehicle is under the action of the engine brake.

The details as well as other features and advantages of this invention are set forth in the remainder of the specification and are shown in the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic diagram of a speed change control device according to this invention.

Figs. 2A - 2C are diagrams describing characteristics of an automatic transmission to which this invention is applied according to different operation modes.

Fig. 3 is a flowchart describing a process of determining a speed range performed by the speed change control device in the manual operation mode.

Fig. 4 is similar to Fig. 3, but showing a second embodiment of this invention.

Fig. 5 is similar to Fig. 3, but showing a third example of this invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to Fig. 1 of the drawings, a speed change control device according to this invention is provided with a controller 10 and a step motor 31 which perform speed change control of a V-belt continuously variable transmission.

The V-belt continuously variable transmission comprises a primary pulley joined to the engine via a torque converter, a secondary pulley joined to a propeller shaft which rotates the wheels and a V-belt looped around these pulleys as disclosed in the aforesaid Tokkai Hei 7-301297 as well as USP5,178,044, USP 5,313,125. A desired speed change ratio is obtained by varying the groove width of these pulleys, the groove width being varied according to the angular position of the step motor 31.

The controller 10 comprises a microcomputer comprising a central processing unit (CPU), read-only memory (ROM), random access memory (RAM) and input-output interface (I/O interface).

Signals are input to the controller 10 from a primary pulley rotation speed sensor 11 which detects a rotation speed N_{pri} of the primary pulley, a secondary pulley rotation speed sensor 12 which detects a rotation speed

Nsec of the secondary pulley, a vehicle speed sensor 13 which detects a vehicle speed *VSP*, a throttle opening sensor 14 which detects a throttle opening *TVO* of an engine, an inhibitor switch 15 which detects an automatic operation mode designated by the lever attached to the continuously variable transmission, an M range switch 16 which detects a selection of a manual operation mode of the continuously variable transmission, and a speed change command detection switch 17 which detects a speed change ratio command input value corresponding to a shift-up operation frequency and a shift-down operation frequency in the manual operation mode.

The speed change ratio command input value in the manual operation mode comprises six speeds from a first speed *M1** to a sixth speed *M6**.

In the manual operation mode, one operation of the lever inputs a command to shift-up or shift-down to an adjacent speed change ratio according to the operation direction thereof. For example, at a fourth speed *M4*, a shift-down command to the first speed *M1* is input by performing three shift-down operations in succession, and then the speed change command detection switch 17 detects a speed change ratio command input value corresponding to the first speed *M1*.

The M range switch 16 and speed change command detection switch 17 are both attached to the operating lever of the transmission. The operation of this lever enables the driver to perform the selection of the manual operation mode and shift-up or shift-down in the manual operation mode. The automatic operation modes comprise a parking mode *P*, reverse mode *R*, neutral mode *N*, forward ordinary travel mode *D* and forward high performance travel mode *Ds*. The forward high performance travel mode *Ds* is a mode which keeps the engine rotation speed higher than the forward ordinary travel mode *D*.

Based on these input signals, the controller 10 calculates a target speed change ratio of the continuously variable transmission, and outputs a corresponding drive signal to the step motor 31.

Describing the construction of the controller 10 from a functional viewpoint, as shown in Fig. 1, the controller 10 comprises an M range speed change ratio determining unit 20, a target primary rotation speed computing unit 21, a final target speed change ratio computing unit 22, a speed change ratio limiter unit 23, a transient target speed change ratio computing unit 24, a real speed change ratio computing unit 25, a target speed change ratio deviation computing unit 26, a time constant computing unit 27, a time constant lower limit limiting unit 28, a time constant variation speed upper limit limiting unit 29 and a motor drive signal computing unit 30.

Based on the throttle opening *TVO* detected by the throttle opening sensor 14, and the speed change ratio command input values *M1** - *M6** detected by the speed change command detection switch 17, the M range

speed change ratio determining unit 20 determines speed change ratio command values *M1* - *M6* in the manual operation mode by a process described hereafter. In the calculation of these speed change ratio command values *M1* - *M6*, the throttle opening *TVO* may be replaced by an accelerator depression amount, or by any other parameter which represents the engine load or the intension of acceleration of the driver.

The target primary rotation speed computing unit 21 performs the following processing according to the manual operation mode detected by the M range switch 16. In the automatic operation mode, a target primary rotation speed *Npri** is calculated by referring to a map of contents shown in Figs. 2A and 2B on the basis of the throttle opening *TVO*, vehicle speed *VSP* detected by the vehicle speed sensor 13, and automatic operation mode detected by the inhibitor switch 15.

This map is stored beforehand in the ROM of the controller 10. On the other hand, in the manual operation mode, the target primary rotation speed *Npri** is calculated by referring to a map of contents shown in Fig. 2C based on the speed change ratio command values *M1* - *M6* determined by the M range speed change ratio determining unit 20 and the vehicle speed *VSP*. This map is also stored beforehand in the ROM of the controller 10.

The final target speed change ratio computing unit 22 calculates a final target speed change ratio basic value *i_{po}'* on the basis of the following equation using the target primary rotation speed *Npri**, and the rotation speed *Nsec* of the secondary pulley detected by the secondary pulley rotation speed sensor 12.

$$i_{po}' = \frac{Npri^*}{Nsec}$$

The speed change ratio limiter unit 23 sets a smaller limit value and a larger limit value of the final target speed change ratio based on the operating limits of the hardware involved in speed change. A final target speed change ratio *i_{po}* is calculated by limiting this final target speed change ratio basic value *i_{po}'* to smaller and larger limits. The value is then output to the transient target speed change ratio computing unit 24. All the values referred to as final target speed change ratio *i_{po}* in the following description should be understood to mean values subject to this limit as processed with respect to smaller and larger limiting values.

The real speed change ratio computing unit 25 calculates a real speed change ratio *i_p* by the following equation on the basis of the primary pulley rotation speed *Npri* detected by the primary pulley rotation speed sensor 11 and the secondary pulley rotation speed *Nsec* detected by the secondary pulley rotation speed sensor 12.

$$i_p = \frac{Npri}{Nsec}$$

The target speed change ratio deviation computing unit 26 calculates a difference ei_p between the final target speed change ratio i_{po} processed by the speed change ratio limiter unit 23 and the transient target speed change ratio i_{pT} calculated by the transient target speed change ratio computing unit 24 as described hereafter, by the following equation:

$$ei_p = i_{po} - i_{pT}$$

The time constant computing unit 27 determines the time constant T of speed change control based on the vehicle speed VSP , throttle opening TVO , the selected mode R, N, D or Ds when in the automatic operation mode or the speed change ratio command value M1-M6 when the manual operation mode, and the speed change ratio deviation ei_p . The time constant T is a constant to show the response characteristics of the transient target speed change ratio i_{pT} relative to the final target speed change ratio i_{po} , and is used when the transient target speed change ratio computing unit 24 determines the transient target speed change ratio i_{pT} from the final target speed change ratio i_{po} . Further, the larger the speed change ratio deviation ei_p is, the larger the time constant T .

The time constant lower limiting unit 28 limits the time constant T set in this way so that it is not less than a preset lower limit, and the time constant variation speed upper limit limiting unit 29 sets an upper limit so that the variation rate of the time constant T does not exceed the preset upper limit.

Using the time constant T processed in this way, and the final target speed change ratio i_{po} calculated by the speed change ratio limiter unit 23, the transient target speed change ratio computing unit 24 calculates the transient target speed change ratio i_{pT} by the following equation:

$$i_{pT} = \frac{1}{1+T \cdot s} \cdot i_{po}$$

where, s = Laplacian operator

A motor drive signal computing unit 30 calculates a step motor drive signal to eliminate this difference based on the difference between the transient target speed change ratio i_{pT} and real speed change ratio i_p , and outputs it to the step motor 31.

Next, the process of determining a speed change ratio in the manual operation mode performed by the M range speed change ratio determining unit 20 will be described referring to the flowchart of Fig. 3. This process is invoked when the manual operation mode is selected by operating the operating lever, i.e. when a signal is inputted selecting the manual operation mode from the M range switch 16, and repeated at a fixed interval as long as the manual operation mode is selected. When in this mode, the process execution interval is set at a much shorter interval than the time required for speed change in the transmission when in

the manual operation mode.

First, in a step S51, it is determined whether or not a shift-down has been commanded based on the speed change ratio command input value M1* - M6* detected by the speed change command detection switch 17 and the current real speed change ratio i_p .

When a shift-down has been commanded, the routine proceeds to a step S52, and when a shift-up has been commanded, the process is terminated without executing subsequent steps. Due to this, during a shift-up operation, the input value M1* - M6* detected by the speed change command detection switch 17 is input without modification to the target primary rotation speed computing unit 21 as the command value M1 - M6.

In the step S52, it is determined whether or not a shift-down operation is being performed.

This determination is made by determining whether or not a difference between or ratio of the final target speed change ratio i_{po} and real speed change ratio i_p is larger than a predetermined reference value. Immediately after the manual speed change mode is selected, the speed change ratio command value M1 - M6 has not yet been entered in the time constant computing unit 27 and the shift-down operation has not yet started.

As a result, the determination result of the step S52 is negative in this case. This result may also be negative when a shift-down operation has been completed.

In either of the above cases, after having reset the initial flag C to 0 in the step S53, the current gear $CurGp$ is set one step lower in a step S58, and the process is terminated. It should be noted that a lower gear means a larger speed change ratio.

On the other hand once it is determined in the step S52 that a shift-down operation is being performed, it is then determined whether or not the engine brake is operating in a step S54. This determination is made by determining whether or not the throttle opening TVO is equal to or less than a preset value TVO_0 . In other words, when the throttle opening TVO is equal to or less than the set value TVO_0 , it is determined that the engine brake is operating.

When it is determined that the engine brake is not operating, the current gear $CurGp$ is set one step lower in the step S58, and the process is terminated.

When it is determined that the engine brake is operating, it is determined whether or not the initial flag C is 0 in a step S55. The initial flag C is initialized to 0 when the manual operation mode starts. Therefore, the initial flag C takes the value 0 the first time the process is performed after the input of a shift-down command or shift-up command.

If the initial flag is 0 in the step S55, it is set to 1 in a step S56. Also, the current gear $CurGp$ is set one step lower in the step S58, and the process is terminated.

When the initial flag is not 0 in the step S55, the routine proceeds to a step S57, and the process is terminated maintaining the current gear $CurGp$.

The speed change ratio command value M1 - M6

determined in this way is input to the target primary rotation speed computing unit 21 and the time constant computing unit 27. The target primary rotation speed computing unit 21 calculates the target primary rotation speed N_{pri}^* based on the speed change ratio command value M1 - M6 and vehicle speed VSP as described hereabove. The time constant computing unit 27 determines the time constant T when the speed change ratio corresponding to the command value M1 - M6 is realized.

Subsequent speed change control by the controller 10 is the same as control in the automatic operation mode.

As a result of determining the speed change ratio command value by such a process, when, for example, the driver operates the operating lever three times in succession in the shift-down direction in the manual operation mode while the vehicle is traveling at the fourth speed M4, the speed change ratio command value is determined as follows.

Specifically, a shift-down command is detected in the step S51, and the routine proceeds to the step S52. When the shift-down command is first input, a shift-down operation has not yet been performed so the routine proceeds to the step S53, and after resetting the initial flag C to 0, the speed change ratio command value is set from the current fourth speed M4 to the third speed M3, and the process is terminated. As a result, the controller 10 performs a shift-down to the speed M3.

On the next occasion the process is executed, as a shift-down is being performed from the fourth speed to the third speed, the process proceeds from the step S52 to the step S54. When the engine brake is not operating in the step S54, the speed change ratio command value is changed to the second speed M2 which is the adjacent larger speed change ratio in the step S58. On the other hand, when the engine brake is operating, the initial flag C is determined in the step S55. As the initial flag C was reset to 0 on the immediately preceding occasion the process was performed, the process proceeds to the step S56.

In the step S56, the initial flag C is set to 1, and the speed change command value is changed to the second speed M2 in the step S58 and the process is terminated.

On the subsequent occasion when the process is executed, the initial flag C is not 0, the process proceeds to the step S57 from the step S55, and the process is terminated with the speed change ratio command value being held at the second speed M2.

Therefore, only two inputs out of three shift-downs are reflected by a speed change ratio command value. A speed change is performed from the fourth speed M4 to the second speed M2, but provided that a shift-down operation and the engine brake is operating, the third shift-down input is ignored, and a speed change to the first speed M1 is not performed. A shift-down input to the first speed M1 becomes possible only after the

speed change ratio corresponding to the second speed M2 is achieved, and it is determined that a shift-down is not being performed in the step S52.

In this way, by limiting shift-down inputs to a maximum of two, the driver is prevented from experiencing an excessive engine brake sensation.

A second embodiment of this invention relating to the limiting algorithm of shift-down operation will now be described referring to Fig. 4.

In the aforesaid first embodiment, the change of speed change ratio relative to a continuous shift-down input was limited to two times, however according to this embodiment, a shift-down limit speed change ratio is set according to the speed change ratio before the shift-down operation is started, and speed changes exceeding this shift-down limit speed change ratio are restricted even when shift-down inputs are performed in succession.

For this purpose, the steps S53, S55 and S56 of the first embodiment are discarded, a new step S101 is provided between the steps S52 and S54, and a new step S102 is provided between the steps S54 and S57. In this process, when it is determined that a shift-down operation is being performed in the step S52, the shift-down limit speed change ratio is set in the step S101 depending on the details of the shift-down input as follows.

Shift-down input	Shift-down limit speed change ratio
M6 → M5	M3
M5 → M4	M3
M4 → M3	M2
M3 → M2	M2
M2 → M1	M1

Here, the contents of shift-down input are based on a speed change ratio when it was first determined that a shift-down was commanded in the step S51. For example, when a shift-down is input at the fourth speed M4, a shift-down to the third speed M3 from the fourth speed M4 is commanded regardless of the number of times the operating lever is operated continuously, and, in this case, the shift-down limit speed change ratio is set to the ratio corresponding to the second speed M2.

To permit such a setting, the speed change ratio when the determination result of step S51 was affirmative for the first time, is stored, and determination of the shift-down limit speed change ratio in the step S101 is performed based on this stored speed change ratio. This processing is made possible by, for example, providing steps between the step S51 and step S52 firstly for determining whether or not the determination result

of the step S51 is the same as on the immediately preceding occasion, and secondly for storing the current speed change ratio when the determination result is negative.

In the above table, the speed change width to the shift-down limit speed change ratio is proportional to the speed change ratio before the shift-down operation is started, i.e., the smaller the speed change ratio before the shift-down operation is started, the larger the speed change width. Herein a smaller speed change ratio denotes a higher vehicle speed. The reason for this is as follows. The engine brake power which acts during a shift-down from third speed to second speed, for example, is larger than the engine brake power which acts during a shift down from sixth speed to fifth speed. Therefore, in order not to let the driver experience an excessive engine braking sensation, shift-down through plural ratios from speed change ratios corresponding to lower speeds must be limited.

After having set the shift-down limit speed change ratio in this way, it is determined whether or not the engine brake is operating in the step S54, and if the engine brake is operating, it is determined whether or not the current speed change ratio is equal to the shift-down limit speed change ratio in the step S102.

When a shift-down operation is not being performed in the step S52, the engine brake is not being operated in the step S54 or the current speed change ratio is not equal to the shift-down limit speed change ratio in the step S102, there is no risk that the driver will experience an excessive engine braking sensation even if a shift-down is performed. In this case, the current gear *CurGp* is set one step lower in the step S58.

On the other hand when it is determined that the current speed change ratio is equal to the shift-down limit speed change ratio in the step S102, the current gear *CurGp* is maintained in the step S57 and the process is terminated.

By executing the above process repeatedly, when for example, the driver operates the operating lever three times in succession in the shift-down direction during travel at the fourth speed M4, i.e. when a speed change from the fourth speed M4 to the first speed M1 was commanded, a real speed change operation is performed only from the fourth speed M4 to the second speed M2. To perform a shift-down to the first speed M1 after shift down to the second speed M2 was completed, the operating lever must be operated again to perform another shift-down input. The same effect is therefore obtained in this embodiment as in the aforesaid first example.

Next, referring to Fig. 5, a third embodiment of this invention relating to the limiting algorithm of the shift-down operation will be described.

In the aforesaid first embodiment, the change of speed change ratio relative to a continuous shift down input was limited to two, but according to this embodiment, a shift-down to the first speed M1 is prohibited

when the second speed M2 is not achieved in the shift-down operation.

For this purpose, the steps S53, S55 and S56 of the first embodiment are discarded, and a new step S201 is provided between the steps S54 and S57.

In this process, when it is determined that the engine brake is operating in the step S54, it is determined in the step S201 whether or not the current gear *CurGp* corresponds to the speed M2. When the current gear *CurGp* does not correspond to the second speed M2, the current gear *CurGp* is set one step lower in the step S58.

On the other hand when the current gear *CurGp* corresponds to the second speed M2, the current gear *CurGp* is maintained in the step S57 and the process is terminated.

In this example, when speed change to the second speed M2 is not complete, a shift-down input to the first speed M1 is not accepted. The same effect is therefore obtained as in the aforesaid first embodiment.

In all the above examples, this invention is applied to a continuously variable transmission, but it may be applied to transmissions of all types wherein a manual shift operation is transmitted to a transmission via a controller.

Also, instead of comparing the throttle opening *TVO* with the set value *TVO₀* as a method of determining whether or not the engine brake is operating in the step S54, an acceleration sensor 32 may be provided for detecting a deceleration of the vehicle in the forward/reverse direction, and the engine brake determined to be operating when the absolute value of the deceleration *-G* detected by the acceleration sensor 32 is equal to or larger than a set threshold value *G₀*.

Further, the determination of whether the engine brake is operating may be performed more precisely by determining that the engine brake is operating only when the throttle opening *TVO* is equal to or less than the set value *TVO₀*, and the absolute value of the deceleration *-G* is equal to or larger than the threshold value *G₀*.

It should also be noted that, in the description hereabove, the smallest speed change ratio corresponds to the highest speed and the largest speed change ratio corresponds to the lowest speed. Therefore, shift-down denotes a change-over of speed change ratio to a larger one while shift-up denotes change over of the same to a smaller one.

The corresponding structures, materials, acts, and equivalents of all means plus function elements in the claims below are intended to include any structure, material, or acts for performing the functions in combination with other claimed elements as specifically claimed. The embodiments of this invention in which an exclusive property or privilege is claimed are defined as follows:

Claims

1. A speed change controller for outputting a speed change ratio command signal to a transmission of a vehicle for selectively applying plural speed change ratios from a largest speed change ratio to a smallest speed change ratio according to a command input by a driver, said vehicle comprising an engine being capable of exerting an engine brake on said vehicle according to a reduction operation input by the driver, **characterized in that** said controller comprises:
 - an engine brake sensor (14, 32) for detecting whether or not said vehicle is under the action of said engine brake,
 - a real speed change ratio detection sensor (11, 12) for detecting a real speed change ratio of said transmission, and
 - a microprocessor (10) programmed to:
 - determine whether or not said transmission is performing a shift-down operation based on said real speed change ratio and said speed change ratio command signal,
 - determine a shift-down limit speed change ratio based on the speed change ratio before said shift-down operation is performed, and
 - refrain from outputting a speed change ratio command signal corresponding to a speed change ratio larger than said shift-down limit speed change ratio when said vehicle is under the action of the engine brake.
2. A speed change controller as defined in Claim 1, wherein said microprocessor (10) is further programmed to determine said shift-down limit speed change ratio such that the larger the speed change ratio before said shift-down operation is performed, the smaller the difference between said shift-down limit speed change ratio and said speed change ratio before said shift-down operation is performed.
3. A speed change controller as defined in Claim 1, wherein said microprocessor (10) is further programmed to determine said shift-down limit speed change ratio such that a difference between said shift-down limit speed change ratio and said speed change ratio before said shift-down operation is performed is equivalent to a difference corresponding to two consecutive shift-down operations.
4. A speed change controller as defined in Claim 1, wherein said microprocessor (10) is further programmed to determine said shift-down limit speed change ratio equal to be a second largest speed change ratio among said plural speed change ratios.
5. A speed change controller as defined in Claim 1, wherein said engine comprises a throttle for increasing and decreasing output, and said engine brake sensor (14, 32) comprises a throttle opening sensor (14) for detecting that an opening of said throttle is equal to or less than a predetermined threshold value.
6. A speed change controller as defined in Claim 1, wherein said engine brake sensor (14, 32) comprises a deceleration sensor (32) for detecting that a deceleration of said vehicle in the forward/reverse direction surpasses a predetermined threshold value.
7. A speed change controller as defined in Claim 1, wherein said engine comprises a throttle for increasing/decreasing output, said engine brake sensor (14, 32) comprises a throttle opening sensor (14) for detecting that an opening of said throttle is equal to or less than a predetermined first threshold value and a deceleration sensor (32) for detecting that a deceleration of said vehicle in the forward/reverse direction surpasses a predetermined second threshold value, and said microprocessor (10) is further programmed to determine that said vehicle is under the action of said engine brake when said throttle opening is equal to or less than said first threshold value, and said deceleration of said vehicle in the forward/reverse direction surpasses said second threshold value.
8. A speed change controller for outputting a speed change ratio command signal to a transmission of a vehicle for selectively applying plural speed change ratios from a largest speed change ratio to a smallest speed change ratio according to a command input by a driver, said vehicle comprising an engine being capable of exerting an engine brake on said vehicle according to a reduction operation input by the driver, **characterized in that** said controller comprises:
 - means (14, 32) for detecting whether or not said vehicle is under the action of said engine brake,
 - means (11, 12) for detecting a real speed change ratio of said transmission,
 - means (10, S52) for determining whether or not

said transmission is performing a shift-down operation based on said real speed change ratio and said speed change ratio command signal,

5

means (10, S101) for determining a shift-down limit speed change ratio based on the speed change ratio before said shift-down operation is performed,

10

means (10, S102, S57) for refrain from outputting a speed change ratio command signal corresponding to a speed change ratio larger than said shift-down limit speed change ratio when said vehicle is under the action of the engine brake.

(54) Speed change controller for automatic transmission

(57) In a vehicle transmission wherein plural speed change ratios from a highest speed change ratio to a lowest speed change ratio are selectively applied according to a command input by a driver, a real speed change ratio of the transmission is detected. It is determined whether or not the transmission is performing a shift-down based on the input command and the real speed change ratio. A shift-down limit speed change ratio is determined based on the speed change ratio

before the shift-down operation is performed, and when the engine brake of the vehicle is operating, the transmission is controlled so as not to apply a speed change ratio larger than this shift-down limit speed change ratio. Due to this, the driver does not experience an excessive engine braking sensation even when an extreme speed change command is issued.

**ANNEX TO THE EUROPEAN SEARCH REPORT
ON EUROPEAN PATENT APPLICATION NO.**

EP 98 11 2791

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report.
The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
